Abstract

Aims: The aim of this study is to evaluate hearing outcome in the pre- and post-operative after tympanoplasty.

Materials and Methods: The present observations study was conducted on 30 randomly selected patients visited the department of ENT, Nalanda Medical College and Hospital, Patna, Bihar, India. Thirty cases of diagnosed chronic otitis media, aged above 18 years, with a demonstrable conductive deafness not more than 40 dB was included in the study.

Results: The mean age of the patients is 32.16 ± 3.61 years. Female outnumbered male counterpart. Commonest presenting complaints was Otorrhoea (93.3%) followed by Hearing loss (86.7%), Vertigo (53.3%) and Tinnitus is found in (40.0%) of patients. The mean pre- and post-operative outcomes in terms Pure tone (p<0.05), Air-bone gap (p<0.05) and Hearing gain (p<0.05).

Conclusions: The present study concluded that Tympanoplasty is a beneficial procedure for hearing improvement and the eradication of the disease.

Keywords: ENT

Introduction

Chronic otitis media is a widespread disease of developing countries such as India, especially in rural areas, and the prevalence ranges from 2% to 15%.¹

Tympanoplasty is a commonly performed surgical procedure to close perforations of the tympanic membrane in chronic otitis media. It is performed to eradicate disease from the middle ear cleft and to reconstruct the hearing mechanism with or without tympanic membrane grafting.²

Since the fundamental principles of Tympanoplasty were introduced by Wullstein and Zollner, surgery of the ear has been directed toward the restoration of function as well as providing a stabilized trouble-free ear.²

Zollner and Wullstein provided a classification of Tympanoplasty that focused on the type of ossicular chain reconstruction (OCR) needed.

The five types of Tympanoplasty they described refer to the most lateral intact structure on which the conductive mechanism will be constructed.

Type I: indicates all three ossicles to be present and mobile.

Type II: grafts the tympanic membrane to an intact incus and stapes.

Type III: exists when an intact mobile stapes superstructure is present and the tympanic membrane or graft remains directly on the stapes superstructure.

Type IV: describes an absent or eroded superstructure with the graft or tympanic membrane overlying a mobile stapes footplate.

Type V: refers to a fenestration created in the horizontal semicircular canal.

In the present prospective comparative study, we analyzed the pre and post surgery hearing benefit to the patient. We hope the results will enable both patients and surgeons to understand the hearing benefit.

Materials and Methods

The present observations study was conducted on 30 randomly selected patients visited the department of ENT, Nalanda Medical College and Hospital, Patna, Bihar, India.

Inclusion Criteria:
1. Patients above 18 years of age of either sex
2. Patients diagnosed with chronic otitis media
3. Those who give informed consent

Exclusion Criteria
1. Patients who are unfit for surgery
2. Patients who have not signed the informed consent
The study protocol was reviewed by the Ethical Committee of the Hospital and granted ethical clearance. After explaining the purpose and details of the study, a written informed consent was obtained.

**Sample selection**

The sample size was calculated using a prior type of power analysis by G* Power Software Version 3.0.1.0 (Franz Faul, Universität Kiel, Germany). The minimum sample size was calculated, following these input conditions: power of 0.80 and \( P \leq 0.05 \) and sample size arrived were 24 participants. Final sample achieved was 30.

**Methodology**

After taking detailed history and recording demographic data and thorough clinical examination was carried out followed by routine blood investigations, X-ray mastoid, otomicroscopy, and pure tone audiometry. Most of the patients were operated under local anesthesia. Patients were operated under local anesthesia. Postauricular approach was used for tympanoplasty.

**Follow-up**

All the patients are followed after surgery as usual on the 7th and 14th days. But the audiogram was done on 3 and 6 months to assess the outcome.

We used the criteria recommended by the Japan Clinical Otology Committee for calculation of the hearing improvement (Tai, 1998).³

- Using the proportion of patients with a postoperative hearing within 40 dB as the first criterion
- Using hearing gain exceeding 15 dB as the second criterion
- Using postoperative air-bone gap within 20 dB as third criterion

**Statistical Analysis**

The data was coded and entered into Microsoft Excel spreadsheet. Analysis was done using SPSS version 20 (IBM SPSS Statistics Inc., Chicago, Illinois, USA) Windows software program. The variables were assessed for normality using the Kolmogorov Smirnov test. Descriptive statistics included computation of percentages, means and standard deviations. Level of significance was set at \( p \leq 0.05 \).

**Results**

**Table 1:** demographic profile of the study population

| Gender (M/F) | 14 (46.7%) / 16 (53.3%) |

| Age (years) | 32.16±3.61 |

**Discussion**

In the present study, a total of 30 cases, aged above 18 years, with a demonstrable conductive deafness not more than 40 dB and consented to participate in the study procedure underwent tympanoplasty. The patients were followed for a period of 6 months to analyze audiometric outcome and hearing gains.

The mean age of the patients is 32.16 ± 3.61 years. Female outnumbered male counterpart. This was found in agreement with previous studies documented in the literature.⁴⁵

In the present study the commonest presenting complaints was Otorrhea (93.3%) followed by Hearing loss (86.7%), Vertigo (53.3%) and Tinnitus is found in (40.0%) of patients. Similarly Shetty S. (2012) found commonest presenting complaints are ear discharge and hearing loss seen in all the (100%) patients. Tinnitus is found in 15%, pain in the ear in 33.3% and vertigo in 11.3% of patients.⁶

The mean pre- and post-operative outcomes in terms Pure tone (\( p < 0.05 \)), Air-bone gap (\( p < 0.05 \)) and Hearing gain (\( p < 0.05 \)) were found comparable with the results of the studies conducted by Yadav et al.⁷ and Haruqop et al.⁸ Many studies on Tympanoplasty have found place in the literature with varying success rates.⁹¹¹

**Conclusion**

The present study concluded that Tympanoplasty is a beneficial procedure for hearing improvement and the eradication of the disease. But, it is difficult to compare the results of the present study with other studies because of different age groups and sub groups, the definition of success; as many studies did not look at hearing outcome, the technique used and the experience level of the surgeon.
