Abstract
Background: Dengue has a wide spectrum of clinical presentations, often with unpredictable clinical evolution and outcome. While most patients recover following a self-limiting nonsevere clinical course, small proportion progress to severe disease.
Methods: The hospital based study was conducted on patients presenting to tertiary care teaching hospital, who fulfilled inclusion and exclusion criteria were enrolled for the study. A comprehensive history taking, physical examination, and lab investigations were carried out and data were collected in pre-designed proforma.
Results: According to complications, in dengue positive cases, bleeding was the most common complication seen in 48.00% cases while shock, myocarditis, and convulsion were present in 31.00%, 2.00% and 1.00% of cases respectively. Among the dengue negative cases, 60.00% had no complication while shock and bleeding were present in 28% and 12.00% cases respectively.
Conclusion: It concluded that shock was most common complication.
Keywords: Hematocrit, Dengue, Dengue Like Illness

Introduction
Infection with the Dengue virus (DENV) is increasingly recognized as an important arthropod-borne viral infection infecting about 2.5 billion people worldwide; being endemic to over a 100 countries with over 975 million belonging to tropical and sub-tropical countries in Southeast Asia, the Pacific and the America. Dengue virus is a single stranded RNA virus which was first isolated from Japan in 1942 by Hotta; while belonging to Flaviviridae family it is transmitted to humans by infective female of Aedes genus, principally by Aedes aegypti, Aedes albopictus mosquito, Aedes polynesiensis and several species of the Aedes scutellaris complex. There are 4 antigenically distinct serotypes, i.e. DENV-1, DENV-2, DENV-3 and DENV-4, which are evolved from a common ancestor.

Dengue is the most important arthropod-borne viral infection of humans. Each year there are about 50 million dengue infections and about 500,000 individuals are hospitalized with DHF, mainly in Southeast Asia. Dengue has been an urban disease but now has spread to rural areas of India as well.

Dengue has a wide spectrum of clinical presentations, often with unpredictable clinical evolution and outcome. While most patients recover following a self-limiting nonsevere clinical course, small proportion progress to severe disease. Early recognition of dengue is challenging because the initial symptoms are often non-specific.
2. A history of fever as given by the patient or parents or a documented fever > 38-degree Celsius in the first 24 hours after admission.

3. Thrombocytopenia of < 100,000 /cubic mm as documented in the automated counter within 24 hours of admission.

4. Informed consent obtained from the guardians or relatives.

**Exclusion criteria**

1. Patients with a proven bacterial infection as the cause for thrombocytopenia and fever.

2. Patients with a pyogenic focus of infection.

3. Discharge against medical advice or referral to higher center before ascertaining the final outcome.

The study was commenced after obtaining clearance from the institutional ethical committee. Written consent was taken from the parents and those who were not willing excluded from the study. Patients presenting to paediatric hospital, who fulfilled inclusion and exclusion criteria were enrolled for the study. A comprehensive history taking, physical examination, and lab investigations were carried out and data were collected in pre-designed proforma.

**OBSERVATIONS**

**Table 1**: Socio-demographic variable

<table>
<thead>
<tr>
<th>Variable</th>
<th>Dengue Positive</th>
<th>Dengue Negative</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age in Years (Mean±SD)</td>
<td>10.12±3.16</td>
<td>10.22±3.19</td>
<td>0.123</td>
</tr>
<tr>
<td>Male : Female</td>
<td>61 : 39</td>
<td>64 : 36</td>
<td>0.256</td>
</tr>
</tbody>
</table>

Mean age was 10.12±3.16 year in dengue negative cases and10.22±3.19 year in dengue positive cases. This difference was found statistically insignificant (p>0.05). In the present study, male patients outnumber than the female with a male to female ratio of 1.87:1. This difference was found statistically insignificant (p>0.05).

**Table 2**: Distribution of Cases According to Complication

<table>
<thead>
<tr>
<th>Complication</th>
<th>Dengue Negative</th>
<th>Dengue Positive</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No.</td>

<td>No.</td>
</tr>
<tr>
<td>Bleeding</td>
<td>12</td>
<td>12.00</td>
<td>48</td>
</tr>
<tr>
<td>Myocarditis</td>
<td>0</td>
<td>-</td>
<td>2</td>
</tr>
<tr>
<td>Shock</td>
<td>28</td>
<td>28.00</td>
<td>31</td>
</tr>
<tr>
<td>Convulsion</td>
<td>0</td>
<td>-</td>
<td>1</td>
</tr>
<tr>
<td>No Complication</td>
<td>60</td>
<td>60.00</td>
<td>18</td>
</tr>
<tr>
<td>Total</td>
<td>100</td>
<td>100.00</td>
<td>100</td>
</tr>
</tbody>
</table>

According to complications, in dengue positive cases, bleeding was the most common complication seen in 48.00% cases while shock, myocarditis, and convulsion were present in 31.00%, 2.00% and 1.00% of cases respectively. Among the dengue negative cases, 60.00% had no complication while shock and bleeding were present in 28% and 12.00% cases respectively.

On applying the chi-square test, the difference was found statistically highly significant (p<0.001).

**Discussion**

Dengue is a major international health concern that is prevalent in tropical and sub-tropical countries. Since the first confirmed case of dengue in India, during the 1940s, intermittent reports from Delhi, Ludhiana, Mangalore, Vellore and from other states have been published. The diagnosis is by clinical profile but they can present with varied manifestation.

There is a steady increase in the outbreak of dengue fever over the years and so among children. This is due to the rapid urbanization with unplanned construction activities and poor sanitation facilities contributing fertile breeding grounds for mosquitoes. Due to an increase in the awareness among health care professionals following the initial epidemic and the availability of diagnostic tests have contributed to the increased diagnosis.

A outbreak of dengue fever during pre-monsoon and monsoon season reported due to stagnation of water after a bouts of rainfall which facilitate vector breeding. This highlight the preventive measures against dengue fever should be taken during water stagnation periods after the initial bouts of rainfall and at the end of monsoon.

Mean age was 10.12±3.16 year in dengue negative cases and10.22±3.19 year in dengue positive cases. This difference was found statistically insignificant (p>0.05). This may be due to out-door activities of these children, where chances of getting bitten by mosquitoes are more. Similar finding was observed in other studies.

In the present study, male patients outnumber than the female with a male to female ratio of 1.87:1. This difference was found statistically insignificant (p>0.05).

Boys were slightly more affected then girls were also observed by Selvan et al and Sahana et al and similar pattern was seen in the retrospective analysis of the 2006 North Indian Dengue outbreak. This may be due to outdoor activities of these children, where chances of getting bitten by mosquitoes are more.

According to complications, in dengue positive cases, bleeding was the most common complication seen in 48.00% cases while shock, myocarditis, and convulsion were present in 31.00%, 2.00% and 1.00% of cases respectively. Among the dengue negative cases, 60.00% had no complication while shock and bleeding were present in 28% and 12.00% cases respectively.
Raj et al\textsuperscript{11} observed that shock was the most common and difficult to treat complication despite appropriate fluid management in accordance with WHO regimen. 20(10.2\%) children had shock, of which 7 were refractory to fluid therapy and blood products (whole blood, packed cell volume, FFP) given as indicated.

\textbf{Conclusion}

It concluded that shock was most common complication.
