Abstract
This is a hospital based prospective observational study, carried out at Gajara Raja Medical College, Gwalior. All the inborn late preterm babies have been included in the study. Selection of late preterm neonates is done by determination of gestational age.
In our study Neonatal convulsions were more common among the late preterm neonates as compare to term group.
In our study jaundice, septicemia, respiratory distress and hypoglycemia were found as major morbidities, among late preterm the rate was found to be 9%, 7.8%, 7.6% and 6% respectively while in term group the rate was 3.34%, 3.38%, 3.41% and 2.56% respectively. Occurrence of these morbidities among late preterm neonates as compared to term group is at higher aspect.

Keywords: Morbidity, Mortality, Preterm, Term & Neonates

Introduction
Preterm birth is defined as birth of a baby before the end of the 37th week (259th day) of pregnancy from the first day of the last menstrual period. Infants born between the gestational ages of 34 weeks and 0/7 days through 36 weeks and 6/7 days (239th - 259th day) are called near term or late preterm. Late preterm infants account for about 74% of all preterm births and about 8% of all births globally1,2.
The morbidity and mortality pattern in late preterm infants is higher than term infants (gestational age ≥ 37 weeks). The main reason behind that is the relative physiologic and metabolic immaturity, though there is no significant difference in the weight or the size of the two groups. The late preterm infants are at twice to thrice increased risk of morbidities like hypoglycaemia, poor feeding, jaundice, infection and re-admission rates after initial hospital discharge3. The infant mortality rate during first year of life for late-preterm infants is on an average four-fold higher than that for term infants4.

Material & Method
This is a hospital based prospective observational study, carried out at Gajara Raja Medical College, Gwalior for a period of 18 months from July 2016 to Dec 2017.

Inclusion criteria:
Cases: All late preterm neonates (34< 37 weeks of gestation) which were born at the Obstetrics department of GMC, Gwalior from July 2016 to Dec 2017 have been included.
Control: All term neonates which were born during the study period included as control group.

Exclusion criteria:
Preterm babies (<34 weeks of gestation) Out born neonates which were admitted in SCNU and still births have been excluded.

METHOD
All the inborn late preterm babies have been included in the study. Selection of late preterm neonates is done by determination of gestational age.
Gestational age is determined by using Naeglie’s formula, antenatal ultrasound records and by applying Ballard scoring system on newborn. The babies were either shifted to NICU or to mother’s side based on the baby’s condition and was followed up till discharge or death. All the neonates were enrolled on a structured protocol, which included the data on antenatal care, maternal risk factors, mode and place of delivery, birth weight, gestational age, gender, diagnosis, relevant investigations, duration of stay and outcome. The data was recorded on Proforma and analysed using descriptive statistics. Survival was defined as the discharge of a live infant from the hospital. Our study was to evaluate the short term outcomes of late preterm babies in comparison with term babies.

We compared the mortality and morbidity pattern of preterm neonates with the term counter part, the data of term neonates retrieved from hospital record.

In our study Neonatal convulsions were more common among the late preterm neonates as compare to term group.

Discussion

Out of the total live births, term births (37 weeks /more) were 75.99%, late preterm births were 16.8% and preterm birth below 34 weeks were 7.2%. it indicate s that late Preterm constitutes significant proportion of total birth. There is increase in proportion of late preterm neonates similar to study in USA where as the proportion of late preterm babies has been increased from 6.2 % in 1995 to 7.5 % in 2008, these changes are results of early obstetric interventions, for examples early termination of pregnancy in eclampsia, and other maternal and fetal morbidities.

Among the preterm, 69.98% were late preterm and remaining 30% were less than 34 weeks which is almost close to the study in USA in 2005, where late preterm babies constituted 70 % of premature births and 30 %less than 34 weeks. In our study the commonest maternal risk factor was found to be PIH in 25.2% of late preterm neonate followed by preterm premature rupture of membranes in16.79% of late preterm, similar pattern of maternal risk factors was found in the hospital based prospective study carried out at the Narayana superspeciality hospital, Bangalore, Karnataka, India.

Kramer MS et al, where PIH were present 29.3% of late preterm birth. With reference to the gender, males were more common (57.5%). The preference
for the male child in the society and the biological vulnerability of the males to infection. The males were more common (59%) among the admitted late preterm neonates.

Conclusion

In our study jaundice, septicemia, respiratory distress and hypoglycemia were found as major morbidities, among late preterm the rate was found to be 9%, 7.8%, 7.6% and 6% respectively while in term group the rate was 3.34%, 3.38%, 3.41% and 2.56% respectively. Occurrence of these morbidities among late preterm neonates as compared to term group is at higher aspect.
